#### Abstract

Two new ruthenium(III) complexes of $1^{\text {st }}$ (cefradine) and $2^{\text {nd }}$ (cefoxitin) generation of cephalosprin drugs have been synthesized and well characterized based on physical (molar conductance), spectral (FTIR \& UV-Vis), thermal analysis (TGA \& DTA) and analytical data. Both cefradine (ceph-1) and cefoxitin   (ceph-2) act as a bidentate ligand and the synthesized complexes $\left[\mathrm{Ru}(\mathrm{L})(\mathrm{Cl})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]$ where $[\mathrm{L}=$ cefradine and cefoxitin] are showing octahedral geometry. The analytical data refer to $1: 1\left(\mathrm{Ru}^{3+} / \mathrm{ceph}\right)$ stoichiometry. FTIR analysis confirmed the coordination through the two oxygen atoms of $\beta$-lactam and carboxylate groups. The surface morphology and particle size investigations were evaluated using XRD, SEM and TEM analyses. The antimicrobial effect of ruthenium(III) ion upon complexity with ceph-1 and ceph-2 were assessed against Gram positive (Staphylococcus epidermidis \& Staphylococcus aureus) and Gram negative (Klebsiella spp., Escherichia coli) bacterial strains. The potential anticancer properties of $\mathrm{Ru}^{3+}$ cephalosprin complexes were evaluated in vitro on colorectal adenocarcinoma (Caco-2) and breast cancer (MCF-7) cell lines, indicating that the synthesized $\mathrm{Ru}(\mathrm{III})$ complexes are relatively better cytotoxic agents in comparison with cisplatin standard drug.

## INTRODUCTION

Antibiotics of cephalosporins (cephs) have become a major part of prescription antibiotics for hospitals in rich countries. Cephalosporins are classified by generation. They are prescribed for a wide range of infections every day. There is no doubt that popularity depends on less sensitivity and toxicity risks as well as a wide range of activity. ${ }^{1}$ Cephalosporins are the most common category from antibiotics they are structurally and pharmacologically linked Penicillin. Like cephs
penicillin have a beta-lactam ring structure that interferes with the synthesis of the bacterial cell wall and this is called a bactericide. In general, low-generation cephs are more $G+$ activity and higher-generation cephs more $G-$ activity. The $4^{\text {th }}$ generation drug cepepime is an exception, with $\mathrm{G}^{+}$ activity equivalent to the $1^{\text {st }}$ generation and $G-$ activity equivalent to the $3^{\text {rd }}$ generation cephs. ${ }^{2}$ The $3^{\text {rd }}$ generation cephs are less active against $G+$ cocci. Extensive ceph class restriction significantly reduced nosocomial, plasmid-mediated, cephresistant Klebsiella infection and colonization. ${ }^{3}$

[^0]The $1^{\text {st }}$ generation cephs have a bacterial efficient against $\mathrm{G}+$ cocci and less active against $\mathrm{G}-$ bacteria. ${ }^{4}$ Regarding $2^{\text {nd }}$ generation cephs, there have a higher efficiency against $G$ - bacteria but are lesser active than $3^{\text {rd }}$ and $4^{\text {th }}$ generations. ${ }^{5,6}$ In literature survey, the ceph-metal chelations were isolated in solid form with $1: 1^{7}$ or 2:1 molar ratio ${ }^{8,9}$ in situ $\mathrm{CH}_{3} \mathrm{OH}^{5,6}$ or in dist. $\mathrm{H}_{2} \mathrm{O} .{ }^{10}$ There are several cephs drugs acts as a good chelating agent towards different metal ions like cefoxitine, ${ }^{6}$ ceftriaxone, ${ }^{5}$ cefradine, ${ }^{10}$ cefixime, ${ }^{11}$ cephalothine, ${ }^{12}$ cefotaxime, cefalaxin, cephamandole, ceftazidime, cephapirin, ${ }^{13}$ ceforuxime, ${ }^{14}$ cefadroxil, cefoperazone, ${ }^{15}$ cefaloridine, ${ }^{13}$ cefdinir, ${ }^{16}$ cefazolin ${ }^{16,17}$ and cefaclor. ${ }^{18}$

According to the vital efficiency of ruthenium compounds against microbial organism and cancer cells, ${ }^{19-21}$ therefore herein in this article, a chemical structures and biological evaluations of the $\mathrm{Ru}(\mathrm{III})$
complexes of cefradine (Fig. 1 ${ }_{\mathrm{a}}$ ) and cefoxitin sodium (Fig. 1 ${ }_{b}$ ) have been reported.

## EXPERIMENTAL

## 1. Chemical

The chemicals $\mathrm{RuCl}_{3} \cdot x \mathrm{H}_{2} \mathrm{O}$, cefradine and cefoxitin sodium were received from Aldrich chemical company (United States) and used without further purification. The solvents were used have an analytical grade.

## 2. Synthesis of Ru(III) cephs complexes

A 50 mL methanolic solutions of cefradine and cefoxitin sodium ( 1 mmol ) were mixed with 20 mL of $\mathrm{RuCl}_{3} . \mathrm{xH}_{2} \mathrm{O}$ (1 mmol ). The dark brown solutions were neutralized at $\mathrm{pH} 7-8$ by 0.1 M of ammonia solution, then refluxed for 3 hrs with continuous stirring. The dark brown precipitates were isolated, washed with few amount of $\mathrm{CH}_{3} \mathrm{OH}$ and dried over anhydrous $\mathrm{CaCl}_{2}$. Despite numerous attempts, we were unable to collect any crystals suitable for X-ray structural analyzes.

#### Abstract

4. Biological assessments

\subsection*{4.1. Antimicrobial test}

Antimicrobial activity of the ruthenium(III) cephs complexes was screened against Gram (+) (Staphylococcus epidermidis and Staphylococcus aureus) and Gram(-) (Klebsiella spp. and Escherichia coli) bacterial strains, using the Kirby-Bauer disc diffusion technique. ${ }^{22,23}$ Anti-cancer assessment of the synthesized ruthenium(III) complexes against colorectal adenocarcinoma (Caco-2) and breast cancer (MCF-7) cell lines was performed according to the standard red uptake assay. ${ }^{24}$

are non-electrolytes, ${ }^{25}$ so the location of chloride ions are inside the coordination sphere, this was supported using a $\mathrm{AgNO}_{3}$ reagent. There are three types of coordination regarding cefradine and cefoxitin drugs towards central metal ions as quadridentate (ONON, OONO or OOON), tridentate (ONO, OOO, NNO or NNN ) and bidentate (NO, OO, or NN) chelation. The molecular modeling study ${ }^{26}$ deduced that no cases of the ligand (ceph-1 or ceph-2) can stereochemically possess as quadridentate or tridentate. The molar ratio between ceph-1 or ceph-2 antibiotic drugs and $\mathrm{Ru}^{3+}$ in neutralized media is $1: 1$ with molecular formula $\left[\mathrm{Ru}(\mathrm{L})(\mathrm{Cl})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]$ where $\mathrm{L}=$ ceph- 1 or ceph-2. The microanalytical analysis of the two new $\mathrm{Ru}(\mathrm{III})$ complexes can be summarized as: [ Ru (ceph1) $(\mathrm{Cl})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}$ ] complex (I, Fig. 2a): $\mathrm{C}_{16} \mathrm{H}_{22} \mathrm{Cl}_{2} \mathrm{~N}_{3} \mathrm{O}_{6} \mathrm{RuS}$, Anal. data: Mwt. $556.40 \mathrm{~g} / \mathrm{mol}$; color: dark brown; yield: 73\%; Calcd (\%): C: 34.54; H: 3.99; N: 7.55; Ru: 18.16; Cl: 12.74, Found (\%):C: 34.30; H: 3.84; N: 7.46; Ru: 18.08; Cl: 12.55. $\left[\mathrm{Ru}(\right.$ ceph -2$\left.)(\mathrm{Cl})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right] \quad$ (II, Fig. 2b): $\mathrm{C}_{16} \mathrm{H}_{20} \mathrm{Cl}_{2} \mathrm{~N}_{3} \mathrm{O}_{9} \mathrm{RuS}$, Anal. data: Mwt. $634.45 \mathrm{~g} / \mathrm{mol}$; color: dark brown; yield: 75\%; Calcd (\%): C: 30.29; H: 3.18; N: 6.62; Ru: 15.93; Cl: 11.18, Found (\%):C: 30.12; H: 3.06; N: 6.43; Ru: 15.73; Cl: 11.07.

Fig. 2a - Speculated structure of $\left[\mathrm{Ru}(\right.$ ceph-1 $\left.)(\mathrm{Cl})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]$ complex.

Fig. $2 \mathrm{~b}-$ Speculated structure of $\left[\mathrm{Ru}(\right.$ ceph-2 $\left.)(\mathrm{Cl})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]$ complex.

## 2. Infrared spectra results

The FTIR spectra of the two new ruthenium(III) complexes in comparison with the free cefradine and cefoxitin drug ligands are displayed in Fig. $3_{\text {a-d }}$ and summarized in Table 1 with some tentative distinguish assignments [2,7,12]. The IR spectra of the cefradine and cefoxitin shows some characteristic bands at $(3347,3289,1771$ and 1677 $\mathrm{cm}^{-1}$ ) and (3486, 3289, 1757 and $1677 \mathrm{~cm}^{-1}$ ) mainly due to the $v\left(\mathrm{NH}_{2}\right), v(\mathrm{NH}), v(\mathrm{COOH})$ and $v(\mathrm{C}=\mathrm{O})$ stretching vibrations, respectively. ${ }^{7-12}$ The ruthenium(III) complexes included the presented bands of free drug ligand (ceph-1 \& ceph-2) and other coordination bands associated after chelation between $\mathrm{Ru}^{3+}$ ions and drug ligand. In the IR spectra of the synthetic $\mathrm{Ru}($ III ) complexes, the band of carboxylic group (1771-1757 $\mathrm{cm}^{-1}$ ) are absent while the bands of asymmetrical vibrations
$v_{\mathrm{as}}(\mathrm{COO})$ at $1589-1574 \mathrm{~cm}^{-1}$, and the bands of $v_{\mathrm{s}}(\mathrm{COO})$ symmetrical vibrations at $1341-1319 \mathrm{~cm}^{-1}$ are present ${ }^{7}$ (Table 1). In case of the FTIR spectra of the prepared complexes, the difference between values of $\left(v_{\mathrm{as}} \mathrm{COO}-v_{\mathrm{s}} \mathrm{COO}\right)$ of the carboxylate groups are similar to the sodium salt, it probably the carboxylate group act as monodentate chelation. Therefore, the carboxyl group is chelated to the ruthenium ion. The band due to $v(\mathrm{C}=\mathrm{O}) \beta$-lactam ring at $1677 \mathrm{~cm}^{-1}$ was found shifted to lower wavenumber ( $30-37 \mathrm{~cm}^{-1}$ ) in the spectra of its $\mathrm{Ru}^{3+}$ complexes. A new absorption band at $600-500 \mathrm{~cm}^{-1}$ is assigned to $v(\mathrm{M}-\mathrm{O})$ of COO and CO oxygens. The absence of $v(\mathrm{M}-\mathrm{N})$ vibration band is confirm the unsharing of the $-\mathrm{NH}_{2}$ group in the coordination with the ruthenium ion.

Table 1
FT-IR assignments of ceph-1 and ceph-2 drugs and its $\mathrm{Ru}^{3+}$ complexes (I \&II)

| Assignments* | Compounds |  |  |  |
| :--- | :---: | :---: | :---: | :---: |
|  | ceph-1 | ceph-2 | I | II |
| $v(\mathrm{C}=\mathrm{O}) ; \mathrm{COOH}$ | 1771 | 1757 | - | - |
| $v(\mathrm{C}=\mathrm{O}) ; \beta$-lactam $+\delta\left(\mathrm{H}_{2} \mathrm{O}\right)$ | 1677 | 1677 | 1640 | 1647 |

## 3. Electronic spectra and Magnetic susceptibility results

The UV-Vis spectra of the ruthenium(III) complexes were recorded in DMSO solution at concentration ( $10^{-3} \mathrm{M}$ ). Complexes I-II show two absorption bands within the range of 420-440 and $630-650 \mathrm{~nm}$, respectively, attributed to intraligand bands. The band within $420-440 \mathrm{~nm}$ range may be due to ligand-to-metal charge transfer (L$\mathrm{M}_{\mathrm{CT}}$ ) transition ${ }^{27-29}$ while the bands at $660-680 \mathrm{~nm}$ range are assigned to spin allowed ${ }^{1} \mathrm{~A}_{1 g} \rightarrow{ }^{1} \mathrm{~T}_{1 g}$ transition. ${ }^{27,28}$ The d-d transition bands ${ }^{2} \mathrm{~T}_{2 \mathrm{~g}} \rightarrow{ }^{4} \mathrm{~T}_{1 \mathrm{~g}}$, ${ }^{2} \mathrm{~T}_{2 \mathrm{~g}} \rightarrow{ }^{4} \mathrm{~T}_{2 \mathrm{~g}}$ and ${ }^{2} \mathrm{~T}_{2 \mathrm{~g}} \rightarrow{ }^{2} \mathrm{~T}_{1 \mathrm{~g}}$ are masked by strong L$\mathrm{M}_{\mathrm{CT}}$ bands. ${ }^{29}$ The $\mathrm{Ru}^{3+}$ metal ions is one of the second transition metal series, which it is always has a low spin with $\mu_{\text {eff }} 1.80$ B.M. ${ }^{30}$ The $\mu_{\text {eff }}$ values for the two synthesized ruthenium(III) complexes located within the range of $1.74-1.78$ B.M. with octahedral configuration ( $d^{5} \& S=1 / 2$ ). ${ }^{31}$ Therefore, the $\mu_{\text {eff }}$ values for these complexes are in accord with the $(+3)$ oxidation of ruthenium.

## 4. Thermogravimetric(TGA/DTA) and kinetic results

The TGA and DTA curves of the free cefradine and cefoxitin sodium drug ligands are shown in Fig. 4(A\&B). Three dissociation stages of both
ceph -1 and ceph -2 ligands are detected in TGA and DTA curves. The thermal cracking beginning from $25^{\circ} \mathrm{C}$ and ends at $800^{\circ} \mathrm{C}$, the observed mass losses for the ceph-1 and ceph-2 are $100 \%$ and $84.95 \%$ against calculated $100 \%$ and $85 \%$, respectively, these are corresponding to the release of $\mathrm{C}_{16} \mathrm{H}_{19} \mathrm{~N}_{3} \mathrm{O}_{4} \mathrm{~S}$ and $\mathrm{C}_{16} \mathrm{H}_{16} \mathrm{~N}_{3} \mathrm{O}_{7} \mathrm{~S}_{2}$ molecules. The results shown that the final product of cefoxitin sodium drug ligand is considered to be $\mathrm{Na}_{2} \mathrm{O}$. In case of cefradine ligand, there is one endothermic peak ( $467{ }^{\circ} \mathrm{C}$ ) and two exothermic peaks (215 and $595^{\circ} \mathrm{C}$ ) but concerning the cefoxitin sodium drug, it contains a three exothermic peaks at 265,447 , $592{ }^{\circ} \mathrm{C}$ in DTA curves due to the chemical events existed in the TGA curves.

TGA and DTA curves of $[\mathrm{Ru}$ (ceph1) $(\mathrm{Cl})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}$ ] complex are displayed in Fig. 4C. The TG and DTA curves display the decomposition of $\mathrm{Ru}^{3+}$ ceph-1 complex in three thermal dissociation endothermic peaks at 148,442 , and $666{ }^{\circ} \mathrm{C}$. The mass loss observed is $82 \%$, showing that organic group $\left(\mathrm{C}_{16} \mathrm{H}_{22} \mathrm{Cl}_{2} \mathrm{~N}_{3} \mathrm{O}_{6} \mathrm{~S}\right)$ is released. The experiment result is similar to the decomposition of the first complex. The final product is considered to be ruthenium metal polluted with few carbon atoms. The TGA and DTG curves of [Ru(ceph$2)(\mathrm{Cl})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}$ ] complex are shown in Fig. 4D. One endothermic peak ( $134{ }^{\circ} \mathrm{C}$ ) and two exothermic peaks at 342 and $708{ }^{\circ} \mathrm{C}$ are observed in the DTA
curve. The first-to-third decomposition stages have a mass loss observed is $73 \%$ against the calculated loss of $73.96 \%$, due to the release of one molecule of ceph-2, chlorine gas and two molecules of $\mathrm{H}_{2} \mathrm{O}$. The final product is considered to be $\mathrm{RuS}_{2}$ polluted with few carbon atoms. Thermal stability of $[\mathrm{Ru}$ (ceph-
2) $\left.(\mathrm{Cl})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]$ complex is more than $[\mathrm{Ru}$ (ceph1) $(\mathrm{Cl})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}$ ] complex. The final product of the two synthesized ruthenium(III) complexes indicted that the different metal ion interaction is exist in coordination environment, because the ruthenium ion changed oxide with heating.

Fig. 4 (A\&B).

Fig. 4 - TGA and DTA curves of (A): ceph-1 drug, (B): ceph-2 drug, (C): $\mathrm{Ru}^{3+}$ ceph-1 complex and (D): $\mathrm{Ru}^{3+}$ ceph- 2 .

Kinetic thermodynamic parameters ( $\mathrm{E}^{*}, \mathrm{Z}$, $\left.\Delta \mathrm{S}^{*}, \Delta \mathrm{H}^{*}, \Delta \mathrm{G}^{*}\right)$ were calculated based on two non-isothermal decomposition methods of CoatsRedfern ${ }^{32}$ and modified Horowitz-Metzger ${ }^{33}$ as listed in Table 2 and displayed in Fig. 5.

Table 2 refer to the kinetic data collected from TG curves, it was found that all compounds have a
negative $\Delta \mathrm{S}$ values except for $[\mathrm{Ru}$ (ceph$2)(\mathrm{Cl})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}$ ] complex, due to the higher $\Delta \mathrm{H}$ value. The greater the thermal stability of a complex, the higher value of the activation energy ( $\mathrm{E}^{*}$ ) for decomposition. ${ }^{34}$

## 5. X-ray powder diffraction, SEM and TEM results

Figure 6 shows the XRD pattern of the solid powder $\left[\mathrm{Ru}(\right.$ ceph-1 $\left.)(\mathrm{Cl})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]$ and $[\mathrm{Ru}($ ceph-2) $(\mathrm{Cl})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}$ ] complexes. The particles size and crystallinity are discussed based on full width at half maximum peak using Debye-Scherer's equation. ${ }^{35}$ The particle size of the tested samples is inserted
between $14-20 \mathrm{~nm}$. XRD of the $\mathrm{Ru}^{3+}$ complexes included three characteristic reflection peaks at $\sim 31$, 44 , and $52^{\circ}$ attributed to (002), (100), and (101) planes regarding ruthenium metal. ${ }^{36}$ It is observed that crystalline size is different for both the complexes, due to change in the cefradine and cefoxitin drug positions.

Fig. 6 - XRD patterns spectrum of the (A): $\mathrm{Ru}^{3+}$ ceph -1 and (B): $\mathrm{Ru}^{3+}$ ceph -2 complexes.

Fig. 7 - SEM images of (A): $\mathrm{Ru}^{3+}$ ceph -1 and (B): $\mathrm{Ru}^{3+}$ ceph -2 complexes.

The SEM images of the two $\mathrm{Ru}^{3+}$ complexes are displayed in Fig. 7. From this figure it can be shown that the average length of grain sizes of the $\mathrm{Ru}^{3+}$ ceph -1 and $\mathrm{Ru}^{3+}$ ceph 2 complexes are $2-5 \mu \mathrm{~m}$, respectively. The surface morphology changes with change in structure of drug ligand, both two images have large number of irregular shaped and some included a regular spherical grain associated with the images refereed in Fig. 7. It is quite clear from SEM results that the average grain size calculated from SEM are quite larger than the average grain size estimated from XRD analysis.

The transmission electron microscopy (TEM) images of $\mathrm{Ru}^{3+}$ ceph-1 and $\mathrm{Ru}^{3+}$ ceph -2 complexes have been given in Fig. 8. The size of the nanoparticles obtained from the XRD diffraction patterns are in close agreement with the TEM studies
which show sizes of about $10-20 \mathrm{~nm}$, which shows the good crystalinity of the nanoparticles.

## 6. Biological results

The comparison of the antibacterial activity of free cefradine and cefoxitin drug ligands with that of ruthenium(III) complexes against different bacterial strains (Table 3), it was found that the cefradine and cefoxitin- $\mathrm{Ru}^{3+}$ complexes have a better biological activity than the free drug ligands. These results can be traced to the active role of the ruthenium metal in increasing the biological efficacy of the drug ligands, due to its ability to penetrate the bacterial cells. ${ }^{37-40}$

Fig. 9 - Relationship between sample concentration and cell viability of $\mathrm{Ru}^{3+}$ complexes and cisplatin against (Caco-2) and (MCF-7) cancer cell lines.

The anticancer activities of ruthenium(III) complexes of ceph-1 and ceph-2 drugs against the colorectal adenocarcinoma (Caco-2) and breast cancer (MCF-7) cell lines are shown in Fig. 9. The $\%$ cell inhibition and $\mathrm{IC}_{50}$ values (43.6, 54, 116, and $45 \mu \mathrm{~g} / \mathrm{mL}$ ) for the $\mathrm{Ru}^{3+}$ ceph-1complex against (Caco-2), $\mathrm{Ru}^{3+}$ ceph-1 complex against (MCF-7), $\mathrm{Ru}^{3+}$ ceph-2 complex against (Caco-2) and $\mathrm{Ru}^{3+}$ ceph-2 complex against (MCF-7) (figure 9) indicate that ruthenium(III) complexes have an efficacy towards the Caco-2 and MCF-7 cancer lines comparable with cisplatin standard drug (5.71 and $3.67 \mu \mathrm{~g} / \mathrm{mL}$ ).

## CONCLUSION

The availability of chemical and biological data presented in this paper is the basis for understanding not only the current state of anti-cancer drugs based on ruthenium(III), but also the rationale for strategies for future drug design. New $\mathrm{Ru}(\mathrm{III})$ nanosized complexes of cefradine and cefoxitin were synthesized. Ruthenium(III) complexes were discussed based on the elemental, molar conductance, thermal and magnetic moment measurements as well as spectral (FTIR, UV-Vis, and XRD) techniques. FT-IR spectra revealed that the ligands reacted as a bidentate ligands through carboxylate oxygen and $\quad \beta$-lactam oxygen groups. The analytical analysis confirmed that the
molar ratio is $1: 1\left(\mathrm{Ru}^{3+} /\right.$ ceph $)$. In vitro antimicrobial activities of $\mathrm{Ru}($ III ) complexes were evaluated towards $\mathrm{G}+\& \mathrm{G}-$ bacteria. The antitumor activities of $\mathrm{Ru}($ III ) complexes are appraised against breast (MCF-7) and colorectal adenocarcinoma (Caco-2) cell lines, which means that the two complexes may be considered promising antimicrobial and anticancer drugs.
